Motivation and Idea

- **Spiking Neural Networks (SNNs)** are bioinspired models capable of generating rich temporal dynamics.
- A single network, modulated by dopamine, can produce **multiple gaits**.
- Dopamine shifts the network between different dynamic attractors.
- **Proposal: Global modulation guides local patterns, enabling adaptive and robust control in quadruped robotics.**

Summary

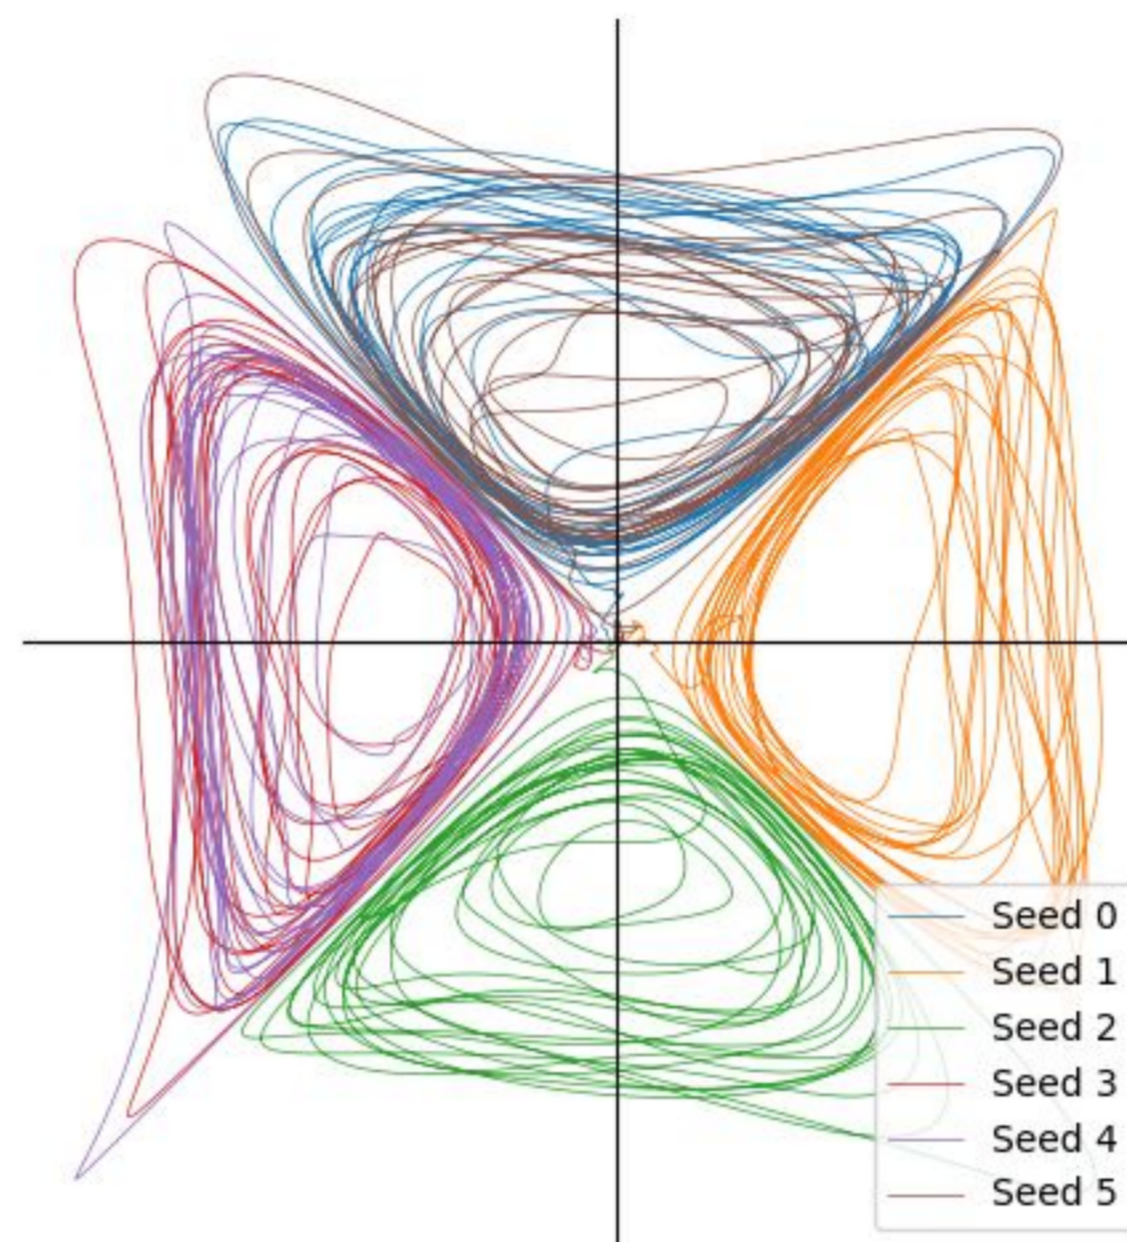

A single spiking neural network, globally modulated by dopamine, generates multiple stable gaits in a quadruped robot

Rich Temporal Dynamics

Clustered connectivity allows the emergence of distinct dynamical regimes.:

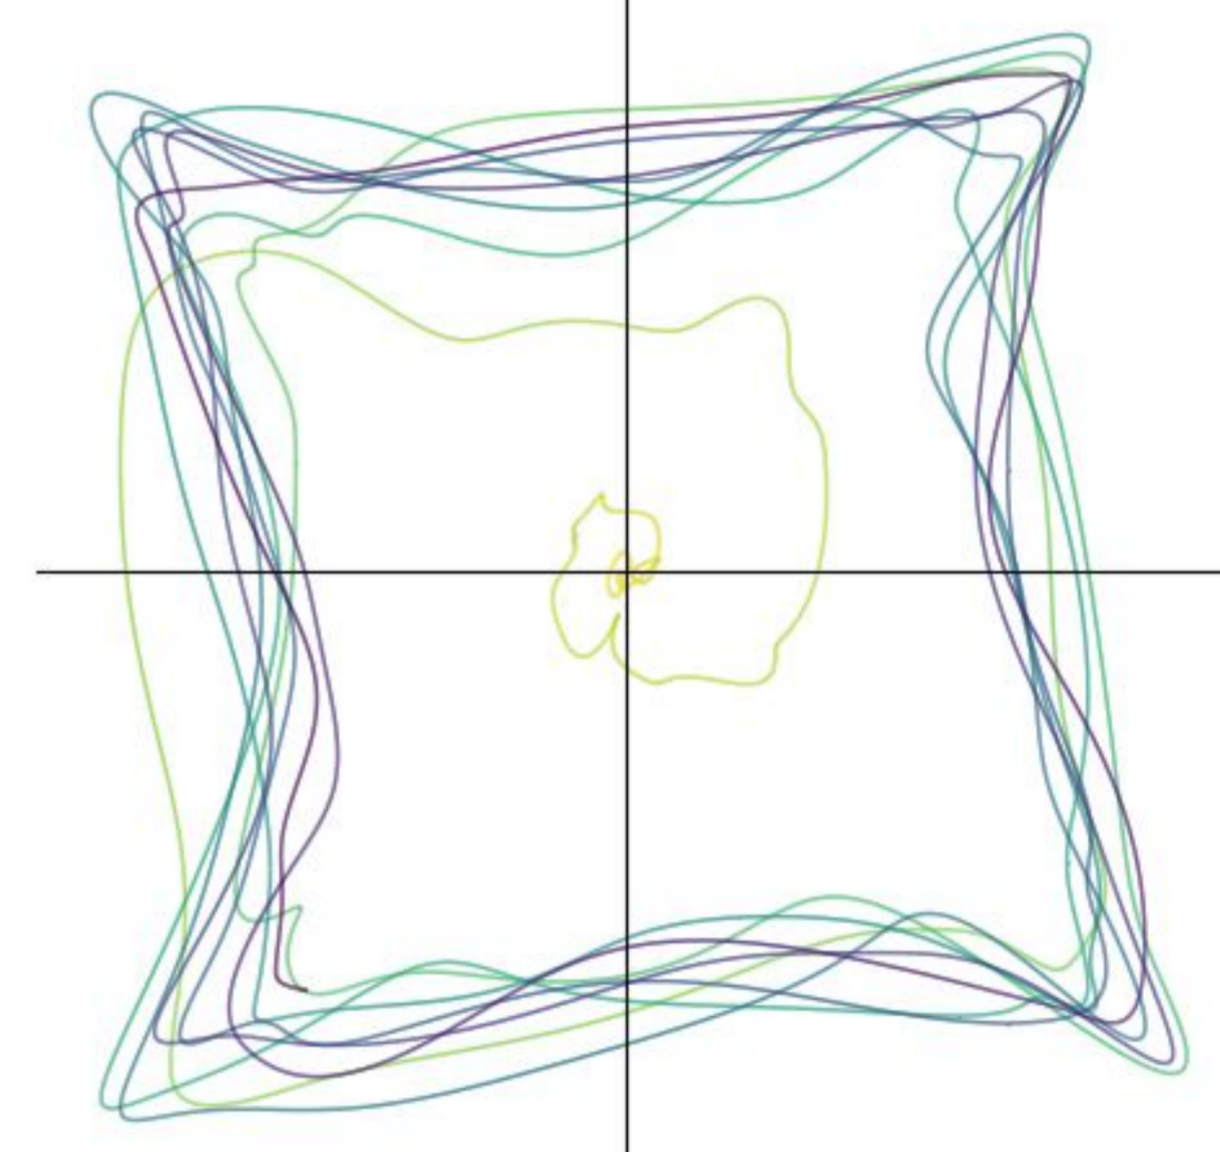

Low dopamine

- chaotic
- exploration

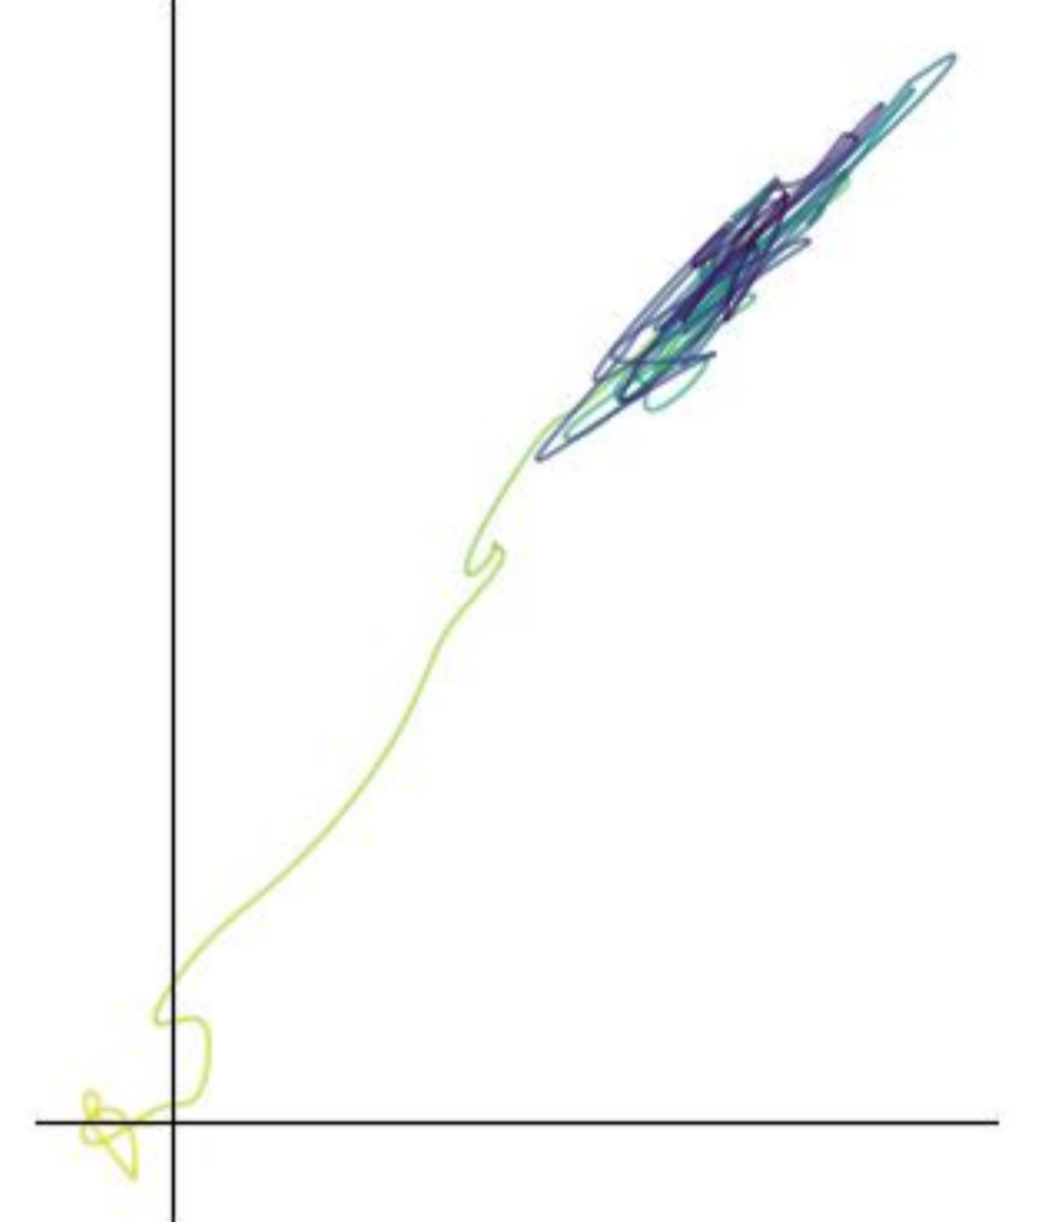

Intermediate dopamine

- cyclic
- stable gait

High dopamine

- resting

Dopamine tunes the network's dynamical regime, balancing exploration and exploitation.

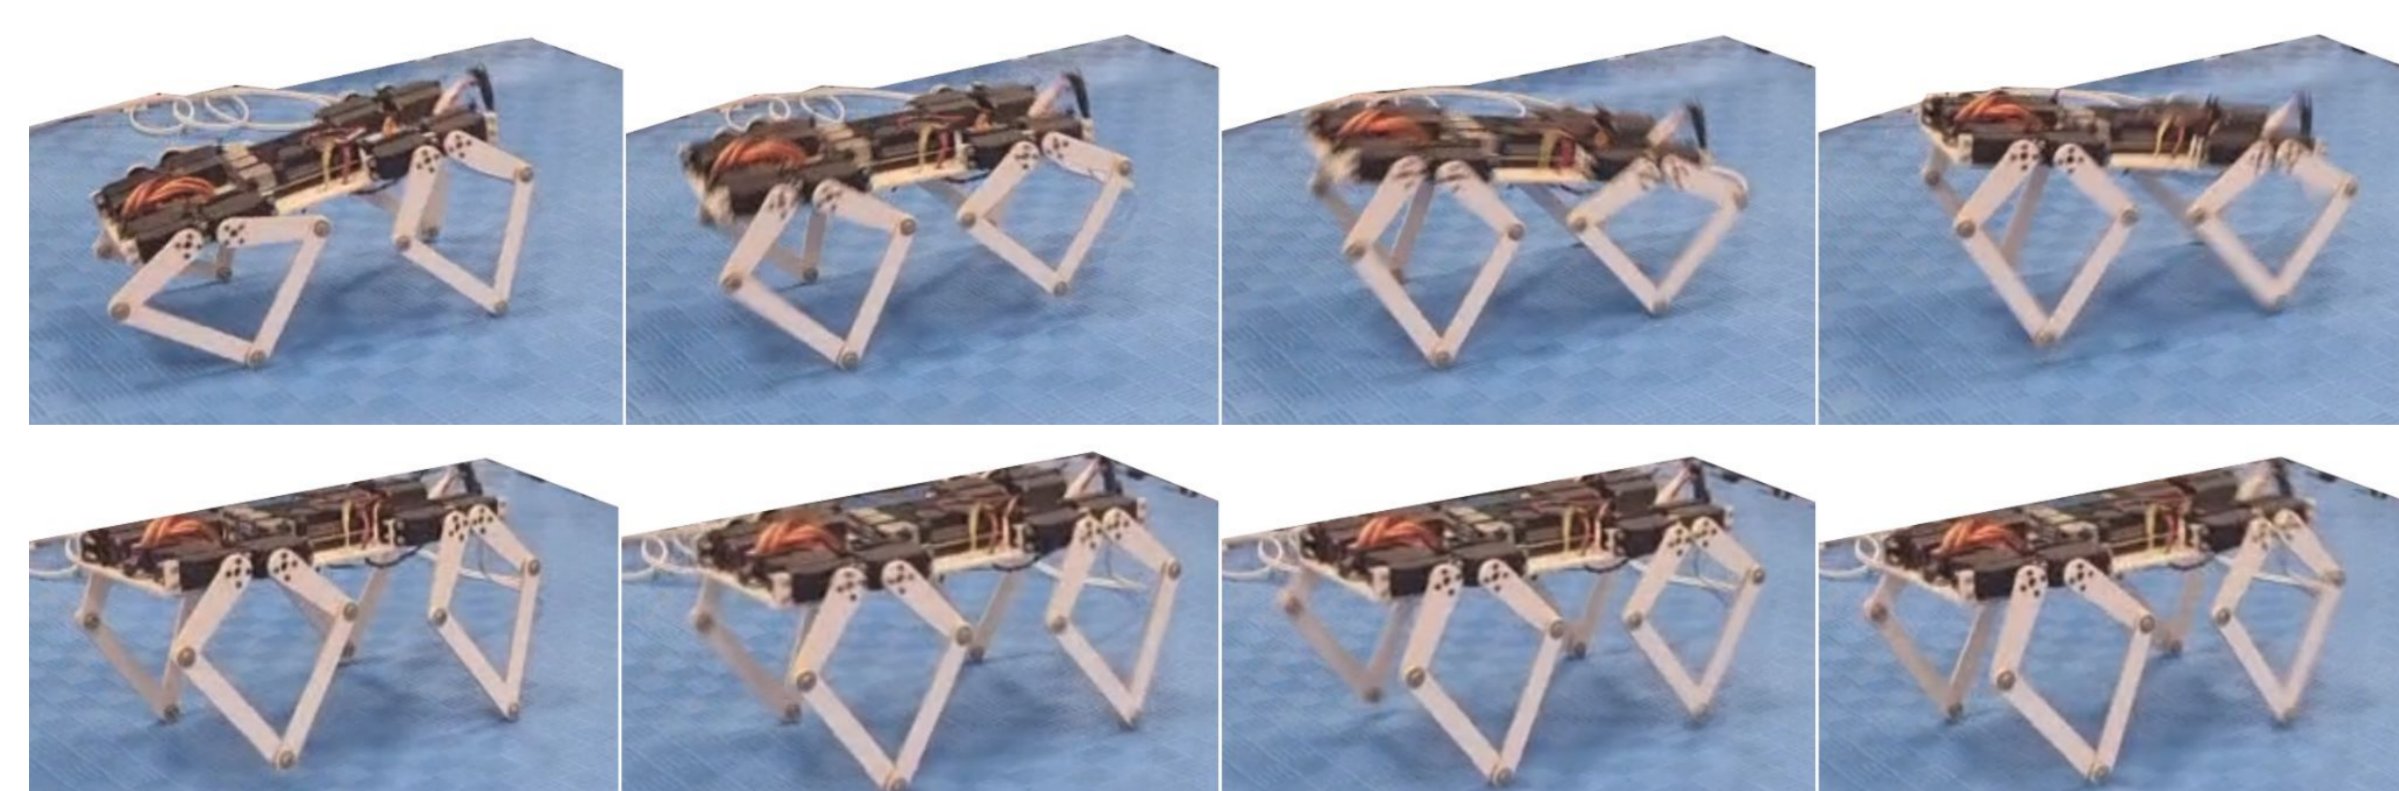

Proposed System

1. Spiking Neural Network

- Excitatory and inhibitory clusters generate oscillations.
- Dopamine modulates inhibition and defines the dynamical regime.

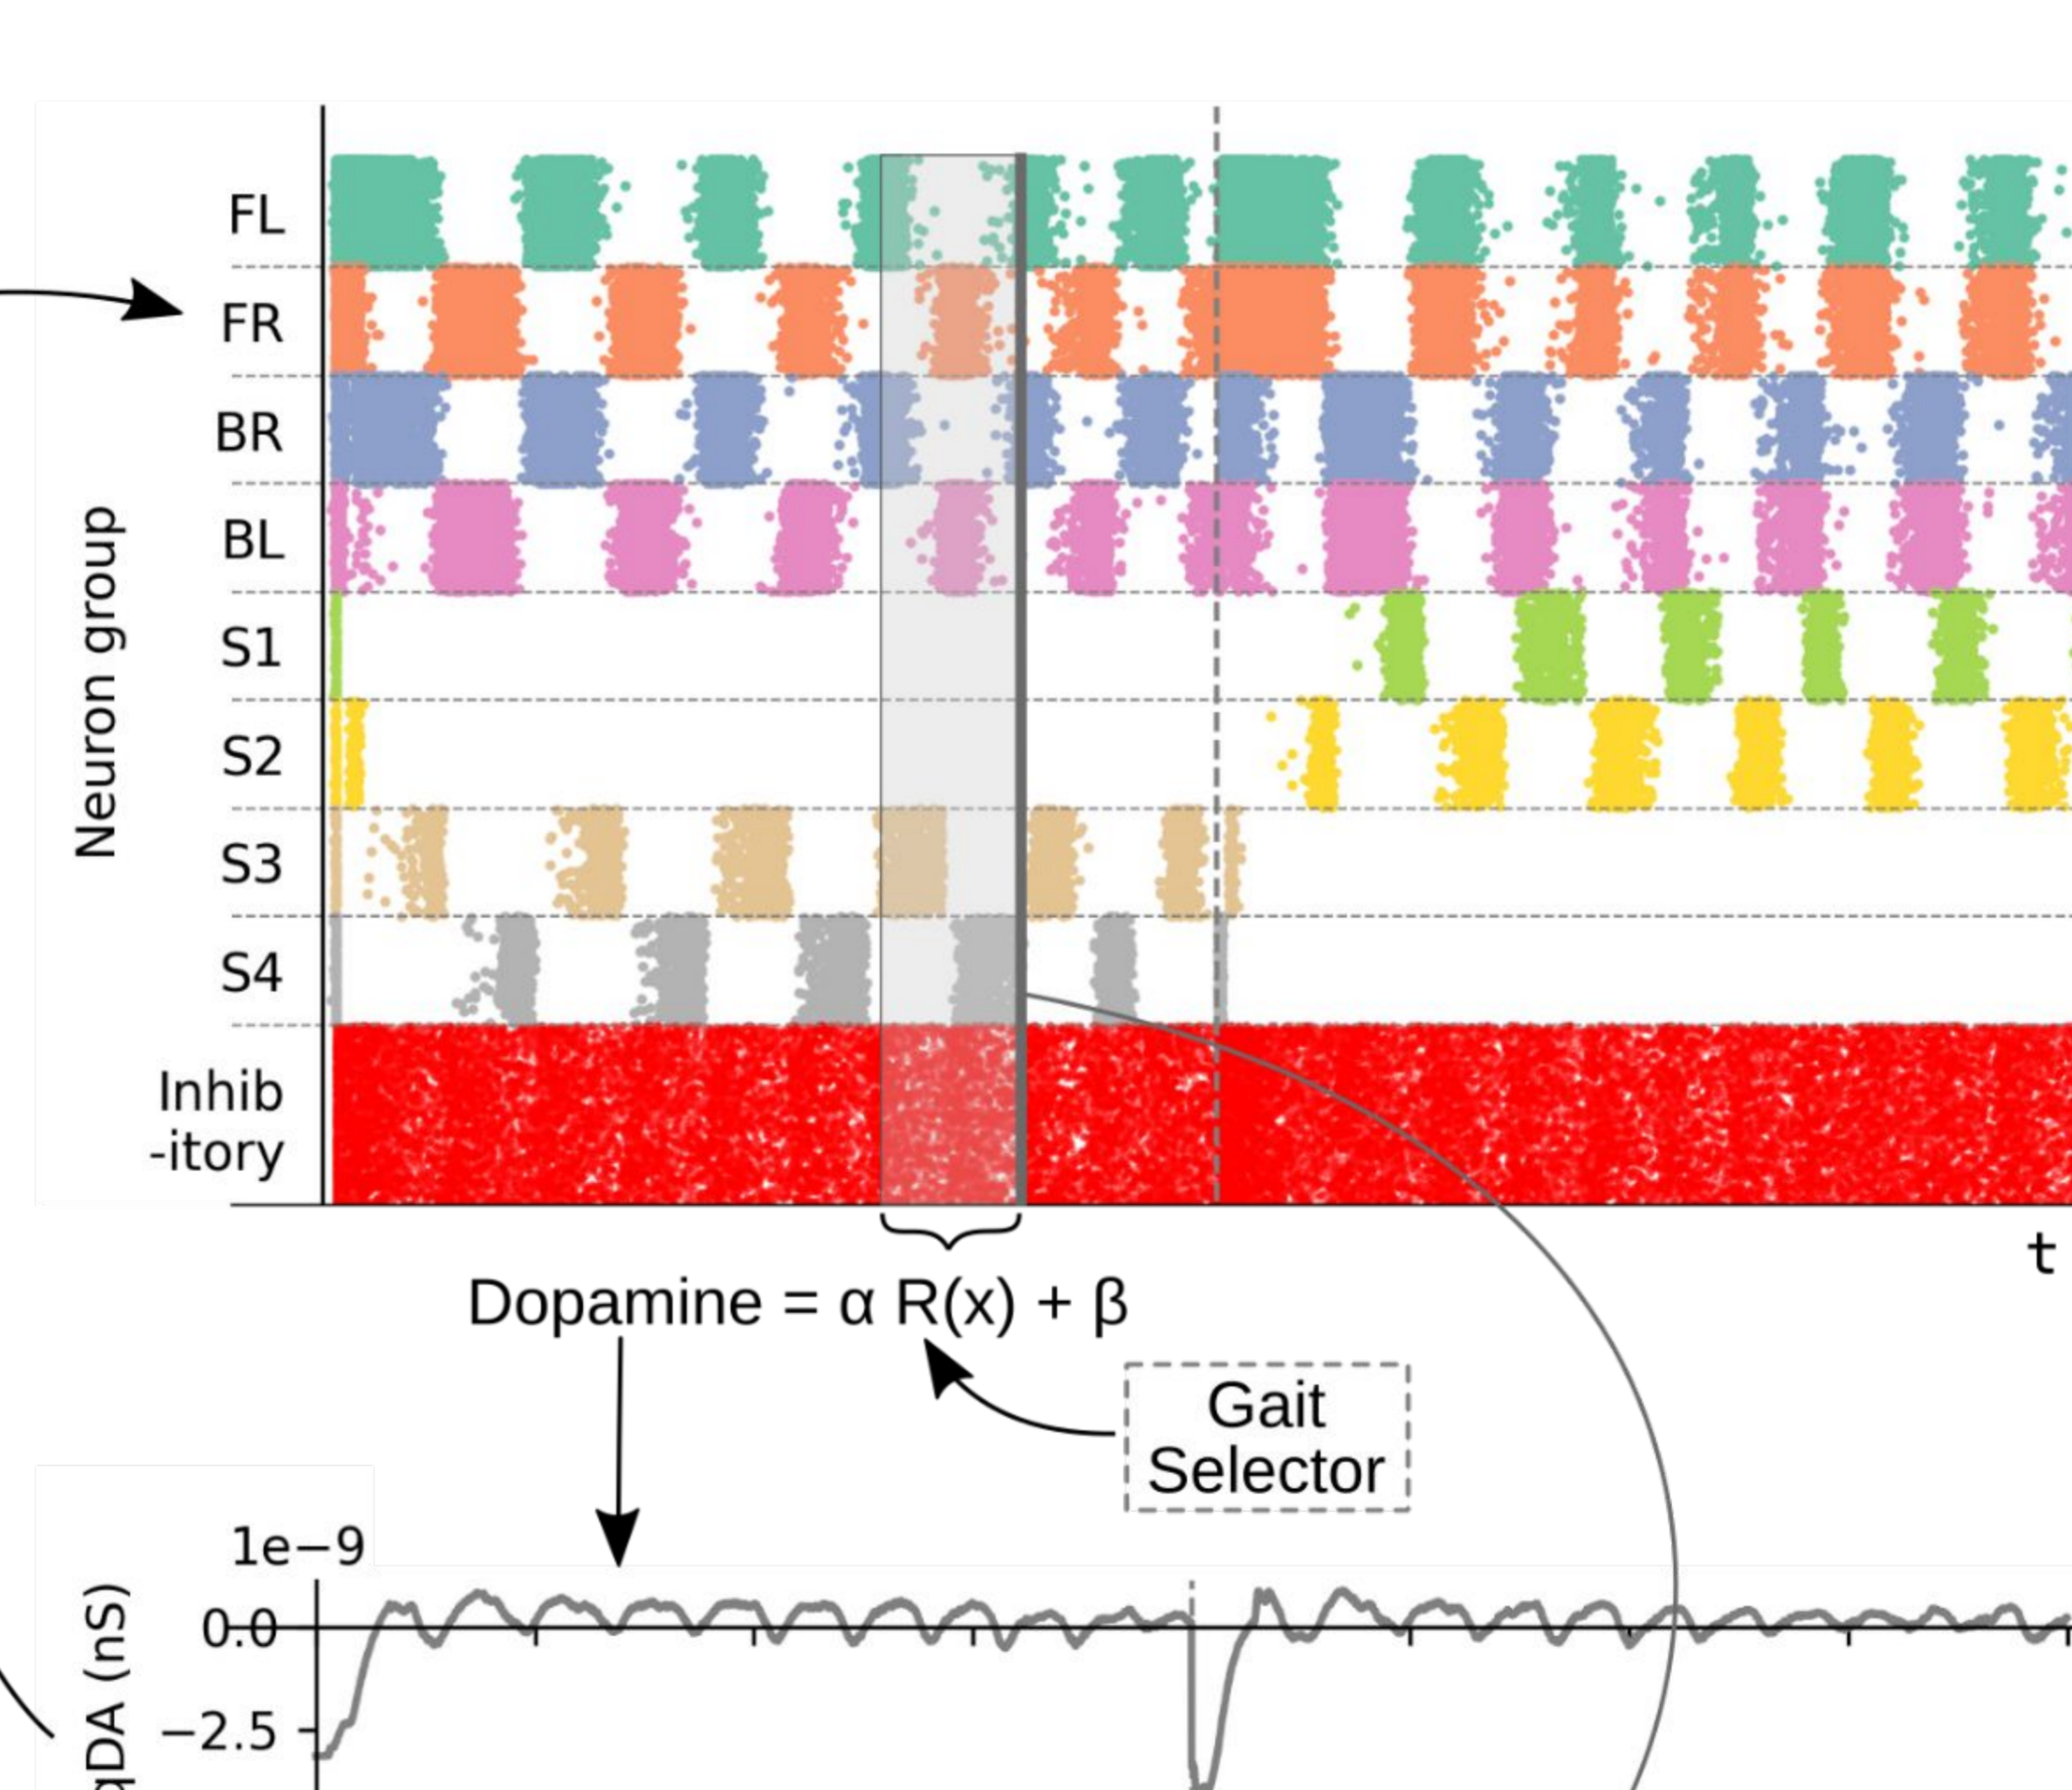

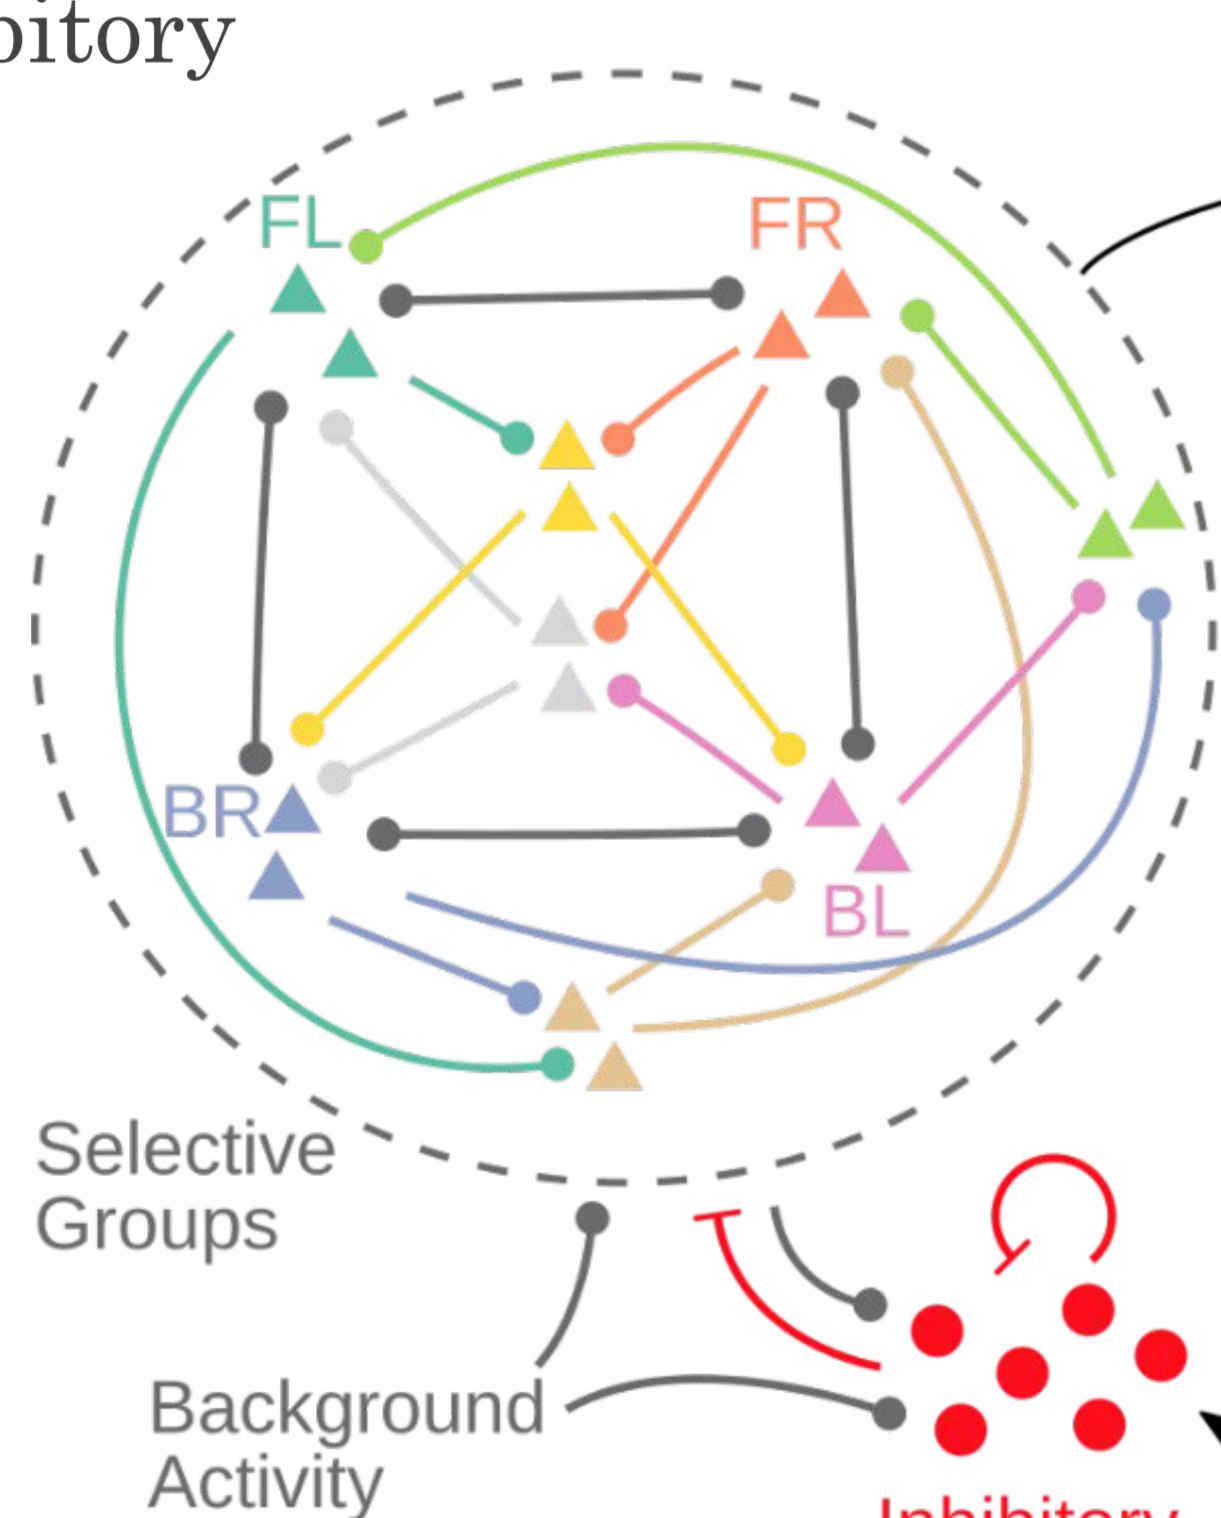

Video

5. Quadruped Robot

- Trajectories are mapped to joint angles.
- The robot performs trot and amble gaits with stable transitions.

2. Neuronal Activity

- Spiking patterns encode gait sequences depending on dopamine and reward

3. Reward Function

- Dynamically adjusts dopamine.
- Low dopamine → exploration.
- Increasing dopamine → convergence to the desired pattern.

4. Leg Trajectories

- Neuronal phases are decoded into stance and swing curves.
- Coordinated locomotion patterns emerge.
